Objectives

- Avoid duplicate XAML with Resources
- 2. Create consistent UI with Styles
- 3. Make your Resources and Styles available across your entire app
- 4. Apply the user's Accessibility choices with built-in Styles

Avoid duplicate XAML with Resources

Tasks

- 1. Use page-level Resources
- 2. Dynamically update Resources

Motivation

◆ Duplicate XAML values are error prone and difficult to maintain

Common to use the same colors and sizes across the UI

Group Exercise

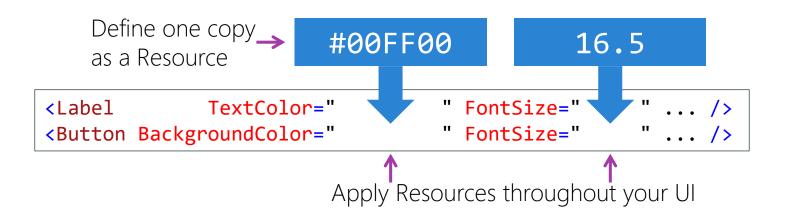

Examine an app containing repeated code

What is a Resource?

❖ A *Resource* is an object that can be used in multiple places in your UI

What is a ResourceDictionary?

* ResourceDictionary is a key/value dictionary that is customized for use with UI Resources

```
Mostly has standard dictionary operations

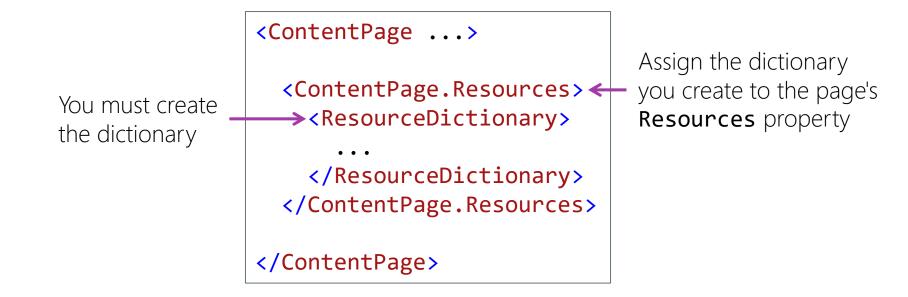

public sealed class ResourceDictionary: ... { ... public object this[string index] { get; set; } public void Add(string key, object value); public void Add(Style implicitStyle); }

Some added UI-specific functionality
```

Page-level Resources

Every page can have a resource dictionary, must be set in code or XAML

Creating Resources

Resources created in XAML must use the XAML-language keyword **x:Key** to set the key

Using static Resources

The **StaticResource** markup extension retrieves a resource, the value is applied once when the target object is created

```
<ContentPage ...>
           <ContentPage.Resources>
             <ResourceDictionary>
Define
             <Thickness x:Key="myKey">10,20,40,80</Thickness>
             </ResourceDictionary>
           </ContentPage.Resources>
         → <StackLayout Padding="{StaticResource myKey}">
           </StackLayout>
         </ContentPage>
```

XAML intrinsic types

❖ The XAML spec defines many types you can use for XAML Resources

```
<ResourceDictionary>
String and
              → <x:String
                              x:Key="...">Hello</x:String>
                   <x:Char
                              x:Key="...">X</x:Char>
Double are
                   <x:Single x:Key="...">31.4</x:Single>
useful since
                →<x:Double
                              x:Key="...">27.1</x:Double>
many UI
                              x:Key="...">8</x:Byte>
                   <x:Byte
properties use
                   <x:Int16
                              x:Key="...">16</x:Int16>
                              x:Key="...">32</x:Int32>
                   <x:Int32
those types
                   <x:Int64
                              x:Key="...">64</x:Int64>
                              x:Key="...">12345</x:Decimal>
                   <x:Decimal</pre>
                  <x:TimeSpan x:Key="...">1.23:5959</x:TimeSpan>
                              x:Key="...">True</x:Boolean>
                   <x:Boolean
                 </ResourceDictionary>
```

Platform dependencies

Can use OnPlatform objects in your resource dictionaries to handle platform-specific values

```
<ResourceDictionary>
  <OnPlatform x:Key="textColor"
    x:TypeArguments="Color"
    iOS="Silver"
    Android="Green"
    WinPhone="Blue" />
  </ResourceDictionary>
```

```
<Label TextColor="{StaticResource textColor}" ... />
```

Platform dependencies

Can use OnPlatform objects in your resource dictionaries to handle platform-specific values

```
<ResourceDictionary>
    <OnPlatform x:Key="textColor"
        x:TypeArguments="Color">
        <OnPlatform="iOS" Value="Silver"/>
        <OnPlatform="Android" Value="Green"/>
        <OnPlatform="Windows" Value="Blue"/>
        <OnPlatform />
        <OnPlatform/>
```

<Label TextColor="{StaticResource textColor}" ... />

Group Exercise

Use page-level Resources

Motivation [delayed availability]

❖ You might download resource values after startup; however, resources applied with **StaticResource** will fail if the key is not in the dictionary

```
<ContentPage ...>
                  <ContentPage.Resources>
                    <ResourceDictionary>
                    </ResourceDictionary>
                  </ContentPage.Resources>
Will throw an
exception if
                → <StackLayout BackgroundColor="{StaticResource bg}">
key not found
                  </StackLayout>
                </ContentPage>
```

Motivation [change]

Resource values might change over time; however, resources applied with **StaticResource** will not update in response to the change

```
<ContentPage ...>
                    <ContentPage.Resources>
                      <ResourceDictionary>
                        <Color x:Key="bg">Blue</Color>
                      </ResourceDictionary>
                    </ContentPage.Resources>
Value applied
once when the -
                  → <StackLayout BackgroundColor="{StaticResource bg}">
object is created
                    </StackLayout>
                  </ContentPage>
```

How to update Resources

❖ Can update resource values from code, useful when you download new values or let the user select preferred colors, font sizes, etc.

Using dynamic Resources

The **DynamicResource** markup extension retrieves a resource when the target object is created and updates it as the value changes

Key not found is OK

❖ DynamicResource leaves the property unset if the key is not found, it is not an error and no exception is generated

```
<ContentPage ...>
                        <ContentPage.Resources>
                          <ResourceDictionary>
             Key not
                         </ResourceDictionary>
             defined
                        </ContentPage.Resources>
No value assigned to
                       →<StackLayout BackgroundColor="{DynamicResource bg}">
BackgroundColor
                        </StackLayout>
                       </ContentPage>
```

Applying Resources in code

Resources can be set in code using **SetDynamicResource**, allows logic to apply different resources based on runtime knowledge

```
var name = new Label { Text = "Name" };

if (Device.OS == TargetPlatform.iOS)
{
   name.SetDynamicResource(Label.TextColorProperty, "hlColor");
}
```

The **BindableProperty** to assign The Resource key to apply

- ① If a ResourceDictionary value is updated at runtime, UI elements using it will update automatically:
 - a) Always
 - b) Never
 - c) Only when using **DynamicResource**

- 1) If a ResourceDictionary value is updated at runtime, UI elements using it will update automatically:
 - a) Always
 - b) Never
 - c) Only when using **DynamicResource**

- 2 To use a **DynamicResource** in code for a UI element named **myElement**, you would call:
 - a) myElement.DynamicResource.Add(...)
 - b) myElement.SetDynamicResource(...)
 - c) DynamicResource.SetOnElement(myElement, ...)

- 2 To use a **DynamicResource** in code for a UI element named **myElement**, you would call:
 - a) myElement.DynamicResource.Add(...)
 - b) myElement.SetDynamicResource(...)
 - c) DynamicResource.SetOnElement(myElement, ...)

Individual Exercise

Dynamically update Resources

Summary

- 1. Use page-level Resources
- 2. Dynamically update Resources

Create consistent UI with Styles

Tasks

- 1. Create and apply a Style
- 2. Use Style inheritance to avoid repeated Setters

Motivation [repeated code]

< Button

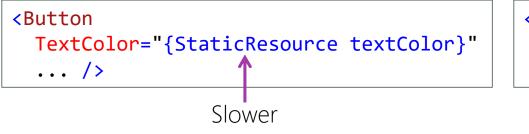

Resources let you avoid duplicate values, but you still have to set each property individually which creates clutter and yields repeated code

```
BackgroundColor="{StaticResource highlightColor}"
                      BorderColor
                                     ="{StaticResource edgeColor}"
                                     ="{StaticResource edgeRadius}"
                                                                         OK
                      BorderRadius
                                     ="{StaticResource edgeSize}"
                      BorderWidth
The property
                                     ="{StaticResource textColor}"
                      TextColor
                                     ="OK" />
                      Text
settings must
be repeated
                    < Button
on each view
                      BackgroundColor="{StaticResource highlightColor}"
                      BorderColor
                                     ="{StaticResource edgeColor}"
                                                                      Cancel
                      BorderRadius
                                     ="{StaticResource edgeRadius}"
                                     ="{StaticResource edgeSize}"
                      BorderWidth
                                     ="{StaticResource textColor}"
                      TextColor
                                     ="Cancel" />
                      Text
```

Motivation [efficiency]

Resource lookup can increase the startup time of your app since the lookup takes longer than assigning a literal value

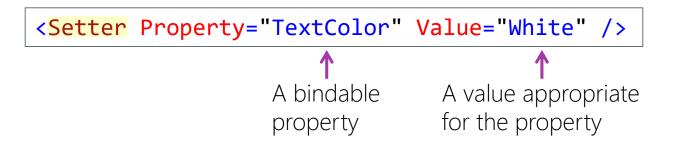

```
<Button
   TextColor="White"
   ... />
   Faster
```

What is a Setter?

❖ A Setter is a container for a property→value pair

What is a Style?

❖ A **Style** is a collection of setters for a particular type of view

TargetType must be set (or runtime exception)

The properties must be members of the **TargetType** class (or runtime exception)

Styles as Resources

Styles are shareable, so they are generally defined as Resources

```
<ContentPage.Resources>
             <ResourceDictionary>
Define in a
             →<Style x:Key="MyButtonStyle" TargetType="Button">
dictionary
               </Style>
             </ResourceDictionary>
           </ContentPage.Resources>
```

Using a Style

Styles are set on a control through the Style property, this applies all the setters in the style to that control

1

The **Style** property is defined in the **VisualElement** base class so it is available in all views.

Combining Styles and Resources

Can use a resource as the Value for a setter, this lets it share a value with other styles

Can use either static or dynamic lookup

Implicit Styles

Styles can be automatically applied to all controls of a target type by omitting x:Key and placing the style into an accessible dictionary

The target type is still specified and is matched exactly, this style will be applied to all buttons in this page

Overriding a setter

Styles provide the default values, explicit property values on the control are applied after the style and take precedence

```
<Style x:Key="MyButtonStyle" TargetType="Button">
     <Setter Property="BackgroundColor" Value="Red" />
  </Style>
  < Button
    Style="{StaticResource MyButtonStyle}"
     BackgroundColor="Blue"√
                                                Cancel
     Text="Cancel"
     .../>
Value set directly overrules the style value
                                            Background is blue, not red
```

Ancestor targeting

❖ A **Style** can target a base type of the object to which it is applied

This style targets VisualElement

```
<Style x:Key="MyVisualElementStyle" TargetType="VisualElement">
     <Setter Property="BackgroundColor" Value="#2A84D3" />
     </Style>
```

```
<Button Style="{StaticResource MyVisualElementStyle}" ... />
```

Can apply to a button since the **Button** class is derived from **VisualElement**

Creating a Style in code

Styles can be created in code to allow runtime customizations

```
var s = new Style(typeof(Button));
s.Setters.Add(new Setter {Property = Button.BackgroundColorProperty, Value = Color.Red});
s.Setters.Add(new Setter {Property = Button.BorderRadiusProperty, Value = 4 });
```

Can then apply Style to a Button directly, or add it to the resources to apply in XAML

Individual Exercise

Create and apply a Style

Motivation [repeated code]

Styles often have duplicate Setters which are then hard to maintain

Motivation [customization]

❖ A provided Style might need some adjustment to meet your needs

Style inheritance

❖ A style can inherit from a base style

Base's TargetType must be the same or a base class

Inherited properties

❖ The new style can modify existing property values and/or add new ones

Individual Exercise

Use Style inheritance to refactor repeated code

Summary

- 1. Create and apply a Style
- 2. Use Style inheritance to avoid repeated Setters

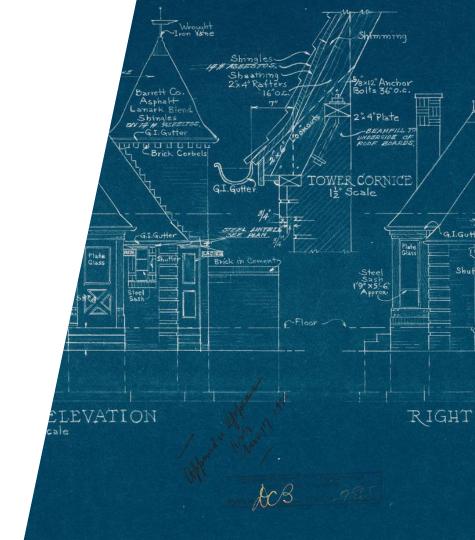

Make your Resources and Styles available across your entire app

Tasks

- 1. Create App.xaml
- 2. Use application-wide resources

Motivation

You will often need to share resources across multiple pages of your app; however, page-level resources are only available on one page

```
<ContentPage ...>
...
...
...
...
...
...
<Button FontSize="{StaticResource size}" />
...
</ContentPage>
```

OK, definition and use are in the same page

Resources defined in one page are not available in a different page

Available dictionaries

- ❖ VisualElement and Application have built-in resource dictionaries
 these are initialized to null by default
- public class VisualElement : ...
 { ...
 public ResourceDictionary Resources
 {
 get;
 set;
 }
 }

Pages, layouts, and views inherit from **VisualElement**

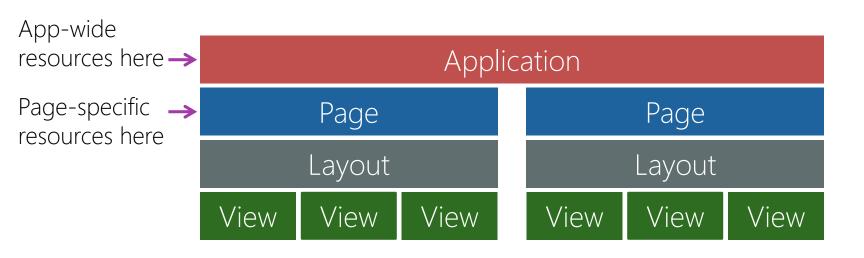

```
public class Application : ...
{ ...
  public ResourceDictionary Resources
  {
     get;
     set;
  }
}
```

Your app class inherits from **Application**

Resource scope

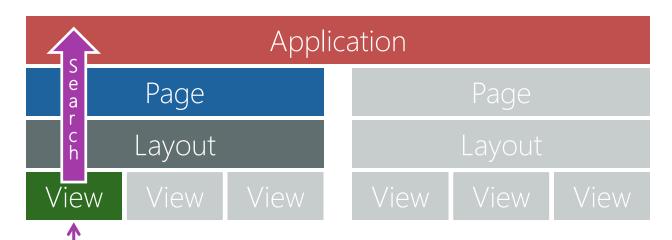

Resources can be defined at different levels so they are scoped to a specific usage area in the application

Lookup rules

❖ Dictionaries are searched starting at the point a resource is applied, then up the visual tree to the Page, and finally to the App

Place resources close to where they are used to minimize lookup cost

Defining application-level resources

App.xaml and App.xaml.cs files are needed in order to use an application-wide resource dictionary in xaml

App.xaml

App.xaml.cs

```
namespace MyApp
{
  public partial class App : Application
  {
    public App()
      {
        InitializeComponent();
        MainPage = new MyPage();
      }
    }
}
```

Using application-level resources

Can use either StaticResource or DynamicResource to apply an application-level resource

```
<ContentPage ...>
    ...
    <Label FontSize="{StaticResource size}" />
    ...
</ContentPage>
```

```
<ContentPage ...>
    ...
    <Button FontSize="{StaticResource size}" />
    ...
    </ContentPage>
```

The resource will be available in all pages of the app

Duplicate keys

Text set

to **One**

Keys can be repeated in different dictionaries, the first matching key on the search path is used

```
<Application.Resources>
  <ResourceDictionary>
    <x:String x:Key="msg">Two</x:String>
                                          App.xaml
  </ResourceDictionary>
</Application.Resources>
<ContentPage.Resources>
  <ResourceDictionary>
    <x:String x:Key="msg">One</x:String>
  </ResourceDictionary>
                                          MainPage.xaml
</ContentPage.Resources>
<Label Text="{StaticResource msg}">
```

Group Exercise

Use application-wide Resources

Merged Dictionaries

Xamarin.Forms allows you to import a dictionary into another dictionary by assigning the MergedWith property of a ResourceDictionary

AboutPage owns a ResourceDictionary

AboutPage

dictionary is referenced by owning class name

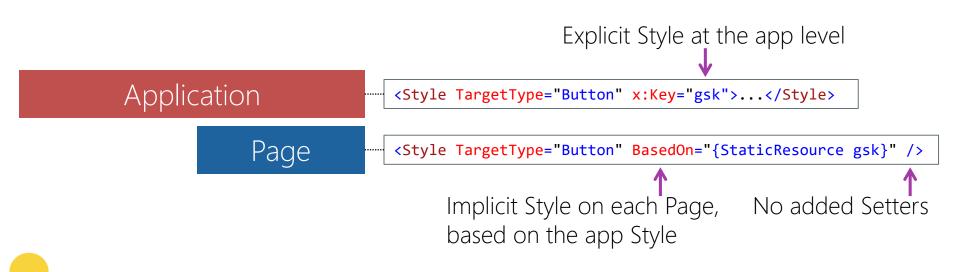

SettingsPage

SettingsPage now has access to resources defined in AboutPage

Guideline for global styles

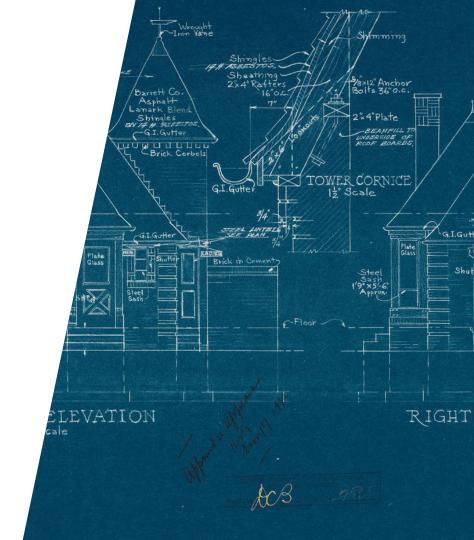

❖ Use explicit styles at the application level and then put an implicit style in each page that uses BasedOn

Summary

- 1. Create App.xaml
- 2. Use application-wide resources

Apply the user's Accessibility choices with built-in Styles

Tasks

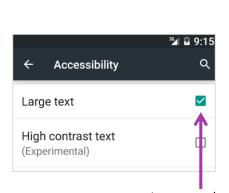

- 1. Apply a built-in Style
- 2. Customize a built-in Style

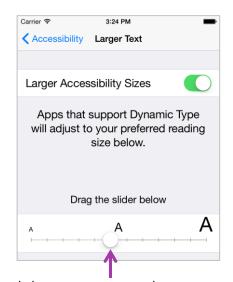

Motivation

Apps should respect the user's device-wide preferences for appearance and accessibility; ideally, apps update their UI when settings change

Apps should try to use the text size the user requested

What is a built-in Style?

❖ Xamarin.Forms maps the user's device-wide preferences to Styles, it keeps those Styles updated as the user changes their settings

Implementation

The built-in styles are provided as Style objects in Device.Styles

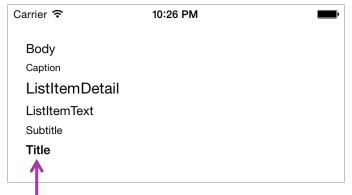

```
public static class Styles
{ ...
  public static readonly Style BodyStyle;
  public static readonly Style CaptionStyle;
  public static readonly Style ListItemDetailTextStyle;
  public static readonly Style ListItemTextStyle;
  public static readonly Style SubtitleStyle;
  public static readonly Style TitleStyle;
}
```

Styles are for common UI like titles, body text, and lists

Targets

❖ The built-in Styles use a TargetType of Label

The Styles have setters for common properties such as fonts and colors

Resource keys

Symbolic constants from **Device.Styles** identify the built-in Styles in XAMI

```
public static class Styles
{ ...
  public static readonly string BodyStyleKey
  public static readonly string CaptionStyleKey
  public static readonly string ListItemDetailTextStyleKey = "CaptionStyle";
  public static readonly string ListItemTextStyleKey = "ListItemDetailTextStyle";
  public static readonly string SubtitleStyleKey = "ListItemTextStyle";
  public static readonly string SubtitleStyleKey = "SubtitleStyle";
  public static readonly string TitleStyleKey = "TitleStyle";
}
```

You use these in your XAML

Using a built-in Style

❖ Must use DynamicResource to access a built-in Style

```
public static class Styles
{ ...
   public static readonly string TitleStyleKey = "TitleStyle";
}

Use the predefined string resource key
<Label Text="Welcome" Style="{DynamicResource TitleStyle}" />
```

DynamicResource is required because these styles are generated via code and can change at runtime if the user changes their preferences

Customizing built-in Styles

❖ BaseResourceKey lets you use a built-in Style as a base, it performs a dynamic lookup which keeps the property values synchronized to the user preferences

Property identifies the Resource to use as the **BasedOn** style (i.e. you are supplying a key that will be used for Resource lookup)

- The built-in Styles work with _____
 - a) Label
 - b) Entry
 - c) ListView
 - d) All of the above

- The built-in Styles work with _____
 - a) **Label**
 - b) Entry
 - c) ListView
 - d) All of the above

- The built-in Styles generally set ______
 - a) Text properties
 - b) Layout properties

- ② The built-in Styles generally set ______
 - a) <u>Text properties</u>
 - b) Layout properties

Summary

- 1. Apply a built-in style
- 2. Customize a built-in style

Thank You!
